Windows File size: 2.33 MBThe present invention relates to a temperature-insulated bridge, particularly for an X-ray beam which is also called X-ray tomography. X-ray tomography is a medical diagnostic method which serves to make available X-ray pictures or X-ray scans of the inside of a patient. In the case of this method, the patient lies on a detector plate or a patient table which is composed, for example, of an array of X-ray detector elements. On the side facing the patient, an X-ray source is positioned. The X-ray source is moved synchronously relative to the patient table along an X-axis which passes through the patient in the case of a tomographic recording. This method is also referred to as computed tomography. In the area of the X-ray source, which is also called fan beam geometry, X-rays are emitted which are polychromatized with energy in the area of the detector elements of the detector plate. An X-ray tube contains the X-ray source. The patient table with the patient is thus exposed to X-rays which are transmitted through the patient and by way of this are adapted to the X-ray attenuation properties of the patient. The transmitted X-rays are received by the detector elements. They are converted into electrical signals which, via a signal processing unit, are converted into tomograms or X-ray images of the inside of the patient. In conventional tomography arrangements, there are disposed on the patient table a so-called ring which surrounds the patient and which contains the X-ray source in order to conduct away from the X-ray source the heat which is produced in the X-ray tube. The ring is thermally coupled with a heat sink of the X-ray tube via suitable heat-conducting elements. There are also known temperature-insulated and water-cooled X-ray tubes which contain therein a cooling device with a coolant pipe, such as, for example, a glycol pipe. A temperature-insulated tube
