The present invention relates generally to electrical connectors and, more particularly, to a modular jack that is designed to transfer data signals between a host device and a connector plug that plugs into the modular jack. Electrical connectors are used in many electronic systems. It is generally easier and more cost effective to manufacture a system as separate electronic assemblies, each containing one or more connectors, rather than as a single electronic assembly containing multiple connectors. Separate connectors in separate electronic assemblies are more readily replaced if one of the electronic assemblies fails. A board-level system typically uses separate connectors for each connector in each assembly that plugs into the system. If any one of these connectors fails, the entire assembly can be replaced. However, such a system is inherently susceptible to the failure of any one of the connectors in a separate assembly. For instance, if the plug is defective, the entire assembly containing the plug must be discarded. An intermediate system connects separate electronic assemblies with a small number of connectors. These connectors are often used to attach an intermediate device, such as a card cage or a daughtercard connector, to the intermediate system. Cards or other electronic assemblies are often slid into and out of the connectors. A problem with this type of system is that the electronic assemblies are often hot-pluggable. Hot-pluggable connectors are often not tested with any special care and are frequently not thoroughly sealed from the surrounding environment, thereby increasing the possibility of EMI and/or RFI emission. Further, these systems do not provide any method for easily isolating the plug from the intermediate system upon mating of the plug with the intermediate system. A small form-factor pluggable system uses a
